The research shows a significant risk of depression of 14.7% (T1), 47.1% (T2) and 20.6% (T3), confirming the estimates indicated by the literature (O'Hara and Swain, 1996). The personal constructs elicited by subjects belonging to the three groups were classified into four personality organizations - Recklessness, Freedom, Power-related, and Belonging-related - and their semantic categories measured. The distribution of these organizations among each subject was obtained as a total score for each organization. To meet the aim of the research, a statistical procedure was developed. The following statistical analysis was carried out on data collected:

- Friedman test, to compare averages in the construct categories on the same subjects;
- Mann-Whitney’s U test to verify if there is a difference in the average semantic of “belonging” between groups of depressed and non-depressed subjects.

The statistical analysis was performed using the statistical program SPSS for Windows 11.4.0. The test results are shown in Table 3.

Subjects of Group 3 (never affected by depression) show a frequency of the categories “power” higher (20.5%) than in the group willing to participate in the subsequent phases of the study (17.1% out of 41 subjects).
